33 **Summary:**

34 Bacteria have evolved multiple defense systems, including CRISPR-Cas, to cleave the DNA of  
35 phage and mobile genetic elements (MGE). In turn, phage have evolved anti-CRISPR (Acr)  
36 proteins that use novel and co-opted mechanisms to block DNA binding or cleavage. Here, we  
37 report that an anti-CRISPR (AcrVA2) unexpectedly inhibits Cas12a biogenesis by triggering  
38 translation-dependent destruction of its mRNA. AcrVA2 specifically clears the mRNA of  
39 Cas12a by recognizing and binding its N-terminal polypeptide. Mutating conserved N-terminal  
40 amino acids in Cas12a prevents binding and inhibition by AcrVA2 but also decreases Cas12a  
41 anti-phage activity. This mechanism therefore enables AcrVA2 to specifically inhibit divergent  
42 Cas12a orthologs while constraining its ability to escape inhibition. AcrVA2 homologs are found  
43 on diverse MGEs across numerous bacterial classes, typically in the absence of Cas12a,  
44 suggesting that this protein family may induce similar molecular outcomes against other targets.  
45 These findings reveal a new gene regulatory strategy in bacteria and create opportunities for  
46 polypeptide-specific gene regulation in prokaryotes and beyond.

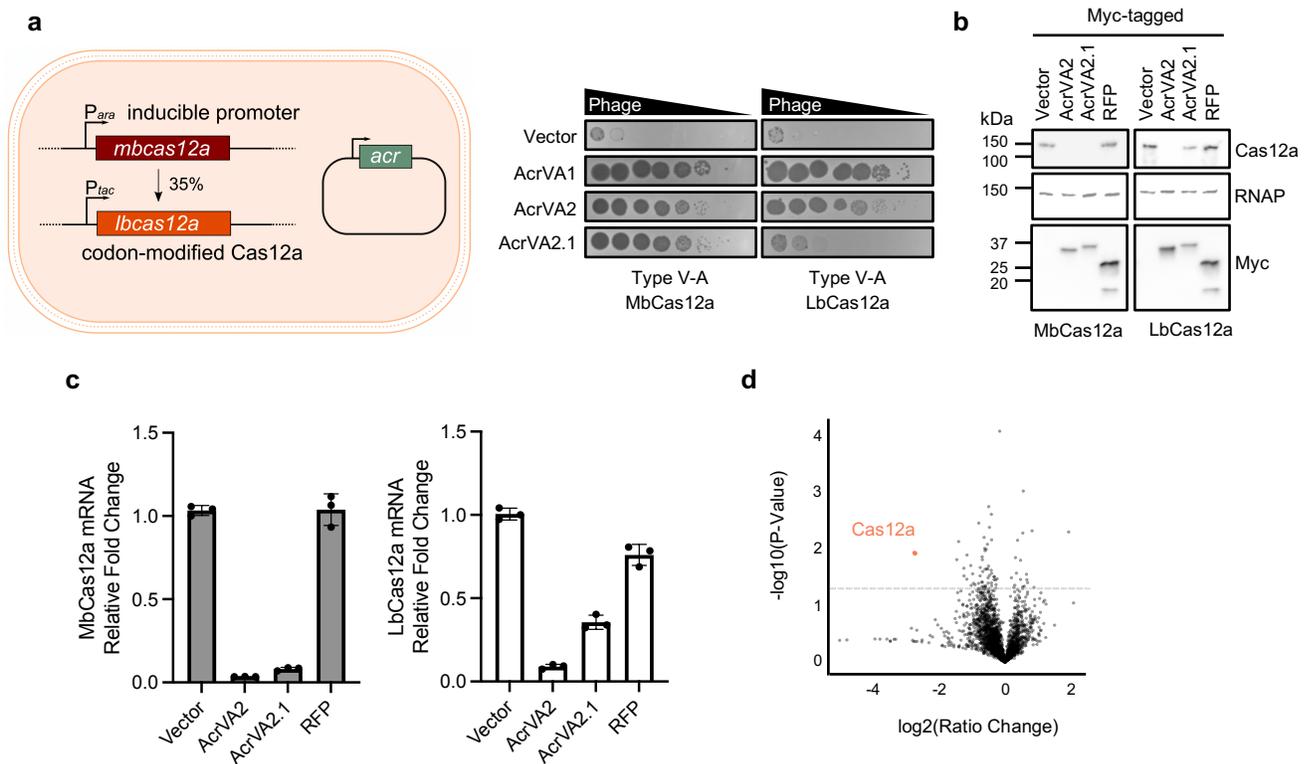

47  
48 **Main:**

49 Bacterial viruses (phages) are the most abundant biological entities on earth<sup>1</sup>. The intense  
50 selective pressure that phages impose on bacteria has spurred the evolution of many bacterial  
51 defense systems, including CRISPR-Cas<sup>2</sup>. In turn, phages have evolved anti-CRISPR (Acr)  
52 proteins to block CRISPR-Cas targeting<sup>3</sup>. Most known anti-CRISPRs inhibit cleavage by binding  
53 CRISPR-Cas complexes directly and preventing target binding or conformational activation,  
54 while others enzymatically modify the complex. The broad-spectrum inhibitor AcrVA1, for  
55 example, inactivates Cas12a by cleaving its CRISPR RNA (crRNA)<sup>4,5</sup>. *AcrVA1* was found  
56 encoded next to another Cas12a inhibitor, *acrVA2*, that is notably large (~1 kb) and widely  
57 distributed across MGEs in diverse classes of bacteria<sup>6</sup>. AcrVA2 potently inhibits MbCas12a  
58 (*Moraxella bovoculi*) in bacteria but not in human cells, but its mechanism has remained unclear.  
59 Here, we show that AcrVA2 recognizes the polypeptide sequence of diverse Cas12a orthologs to  
60 interrupt its biogenesis and trigger mRNA destruction independently of the promoter or codon  
61 sequence.

62  
63 **AcrVA2 specifically downregulates mRNA and protein of divergent Cas12 orthologs**

64 AcrVA2 binds MbCas12a but does not inhibit DNA cleavage *in vitro* (Extended Data Fig. 1),  
65 consistent with its inability to inhibit Cas12a in human cells<sup>6</sup>. This result suggested that AcrVA2  
66 may inhibit Cas12a upstream of ribonucleoprotein (RNP) complex formation. To test this, we  
67 used strains of *Pseudomonas aeruginosa* in which plasmid-borne AcrVA2 robustly inhibits  
68 MbCas12a or LbCas12a expressed from the chromosome via different inducible promoters (Fig.  
69 1a). Intriguingly, AcrVA2 reduced mRNA and protein levels greater than ten-fold for both  
70 MbCas12 and LbCas12a, which share 35% amino acid identity. The degree to which AcrVA2  
71 and AcrVA2.1 (an ortholog with 84% identity) downregulated MbCas12a and LbCas12a  
72 correlated well with their ability to inhibit both orthologs (i.e. AcrVA2.1 was less active against

73 LbCas12a). AcrVA2 downregulates codon-modified Cas12a equally well as native Cas12a (Fig.  
 74 1b,c and Extended Data Fig. 2), indicating that a specific Cas12a nucleotide sequence is not  
 75 required for its downregulation. The codon-modified sequences of LbCas12a and MbCas12a  
 76 were used for the rest of this study.  
 77

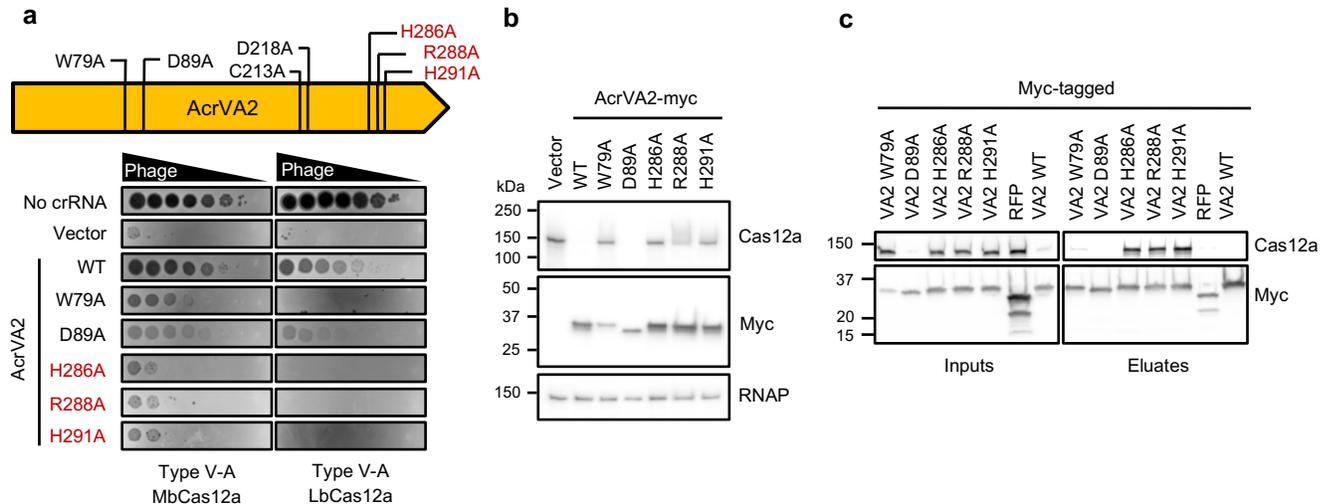

78  
 79  
 80 Figure 1. AcrVA2 specifically downregulates mRNA and protein of divergent Cas12a orthologs. (a) Left: Schematic of  
 81 *Pseudomonas aeruginosa* strains engineered to express MbCas12a or codon-modified LbCas12a from inducible  
 82 promoters and *acr* genes from plasmids. Right: Phage plaque assay with ten-fold serial dilutions of phage to assess  
 83 CRISPR-Cas12a inhibition. (b) Western blot on bacterial lysates to assess the effect of myc-tagged AcrVA2 or  
 84 control proteins on Cas12a expression. RNAP, RNA polymerase (loading control). (c) qRT-PCR on mRNA from  
 85 bacteria expressing Cas12a and AcrVA2 or controls. Error bars indicate standard deviation. (d) Volcano plot for  
 86 transcriptomic analysis. mRNA was extracted from bacteria expressing MbCas12a and AcrVA2 or controls.  
 87  $\log_2(\text{Ratio Change})$  is the mean expression level for samples expressing AcrVA2 or AcrVA2.1 relative to controls  
 88 (see methods for details). Each dot represents one gene. Dotted line indicates p-value of 0.05.

89  
 90 The ability of AcrVA2 to downregulate divergent *cas12a* transcripts expressed from non-native  
 91 promoters and featuring dramatic nucleotide changes prompted us to assess its specificity.  
 92 Transcriptomic analysis revealed that *cas12a* was the only expressed gene that was significantly  
 93 downregulated by AcrVA2 (Fig. 1d), while a hypothetical protein (PA3431) and a PpiC-type  
 94 peptidyl-prolyl cis-trans isomerase (PA3871) were upregulated for reasons that are unclear. A  
 95 closer analysis of the *cas12a* open reading frame revealed that reads were reduced by AcrVA2 at  
 96 the 5' end and were barely detectable for the latter 75% of the gene (Extended Data Fig. 3).

97 Altogether, these results demonstrate that AcrVA2 specifically downregulates divergent and  
98 codon-modified Cas12a orthologs independently of the promoter and codon sequence.

99

## 100 Inactive AcrVA2 mutants stably bind Cas12a protein

101

102 Figure 2. Inactive AcrVA2 mutants stably bind Cas12a protein. (a) Phage plaque assay using ten-fold serial dilution

103 of phage to assess Cas12a inhibition by wildtype or mutant AcrVA2. (b) Western blot on bacterial lysates to assess

104 effect of AcrVA2 point mutants on Cas12a expression. RNAP, RNA polymerase (loading control). (c)

105 Immunoprecipitations on myc-tagged AcrVA2 H286A or GST control from bacterial lysates to assess interaction

106 with Cas12a. Samples were resolved by SDS-PAGE and probed via Western blot.

107

108 AcrVA2 does not appear to have any conserved domains or catalytic residues that suggest a  
109 molecular mechanism for this downregulation. The crystal structure of AcrVA2 revealed three  
110 distinct domains but likewise did not resemble any known enzymes<sup>7</sup>. To identify amino acids in  
111 AcrVA2 that are important for its function, we mutated residues that are highly conserved across  
112 diverse AcrVA2 orthologs, including FinQ from *E. coli*<sup>6,8</sup>. Interestingly, W79A and D89A  
113 mutations caused a moderate loss of function, while H286A, R288A, and H291A substitutions in  
114 the C-terminal region of the protein diminished AcrVA2 activity and restored Cas12a protein  
115 (Fig. 2a,b and Extended Data Fig. 4 ) and mRNA (Extended Data Fig. 3).

116

117 The inability of AcrVA2 mutants to fully downregulate Cas12a in bacteria enabled us to ask  
118 whether these two proteins interact *in vivo*. Immunoprecipitation of myc-tagged AcrVA2  
119 mutants (H286A, R288A, H291A) showed stable co-precipitation with Cas12a (Fig. 2c).  
120 AcrVA2<sup>W79A</sup>, on the other hand, abrogated downregulation of Cas12a but did not yield as robust  
121 an interaction as the C-terminal mutants, suggesting that this residue is important for the  
122 interaction with Cas12a or for AcrVA2 stability.

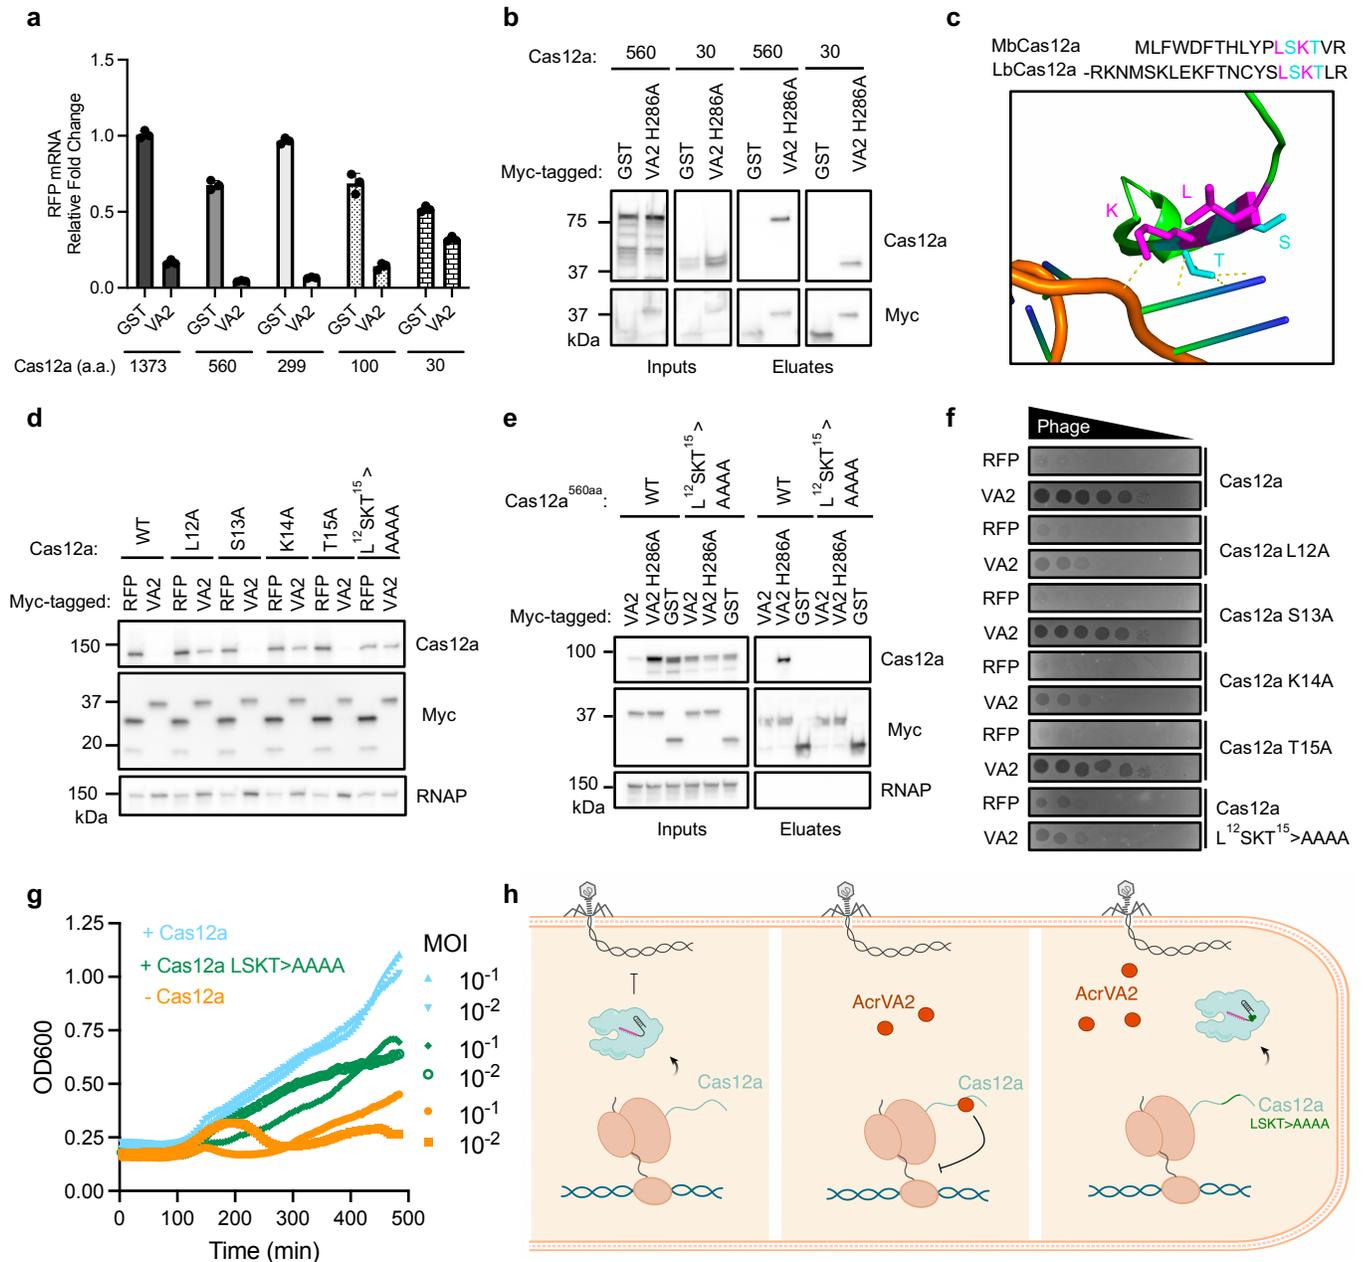

123

124 AcrVA2 binds apoCas12a *in vitro* (Extended Data Fig. 1a) and co-purifies with a fragment  
125 (residues 620-636) from Cas12a<sup>7</sup>. However, a triple mutation in AcrVA2 (E98A/D129A/D195A)  
126 that was previously shown to break this specific interaction did not significantly affect

127 downregulation or inhibition in our *in vivo* assays (Extended Data Fig. 5), indicating that  
 128 interaction at this site in Cas12a is not essential for inhibition. Overall, these results reveal that  
 129 conserved C-terminal residues in AcrVA2 (H286/R288/H291) are important for mRNA  
 130 downregulation and confirm that protein-protein interactions between Cas12a and AcrVA2 are  
 131 not directly inhibitory.

132

133 **AcrVA2 recognizes conserved residues in the Cas12a N-terminal polypeptide**

134

135 **Figure 3. AcrVA2 binds the N-terminal polypeptide of Cas12a to trigger mRNA downregulation. (a)** qRT-  
 136 PCR on mRNA from bacteria expressing truncated Cas12a-RFP fusions to assess downregulation by AcrVA2

137 (VA2) relative to GST control. Numbers indicate amino acid (a.a.) length of Cas12a from N-terminus. Error bars  
138 indicate standard deviation. **(b)** Immunoprecipitations on myc-tagged AcrVA2 H286A or GST control from  
139 bacterial lysates to assess interaction with Cas12a. **(c)** Residues L<sup>31</sup>SKT<sup>34</sup> from a crystal structure of LbCas12a with  
140 crRNA (orange sugar-phosphate helix and blue-green nucleobases)<sup>10</sup>. LK and ST indicated in magenta and teal,  
141 respectively. **(d)** Western blot on bacterial lysates to assess downregulation of wildtype or mutant Cas12a protein by  
142 AcrVA2 relative to RFP control. RNAP, RNA polymerase (loading control). **(e)** Immunoprecipitations on myc-  
143 tagged AcrVA2, AcrVA2 H286A or GST control from bacterial lysates to assess interaction with truncated  
144 Cas12a<sup>560aa</sup>. **(f)** Phage plaque assay on strains expressing wildtype or mutant Cas12a to assess inhibition by AcrVA2  
145 relative to RFP. **(g)** Growth curves of bacteria infected with phage at different multiplicities of infection (MOI).  
146 Bacteria expressed wildtype MbCas12a (blue), MbCas12a L<sup>12</sup>SKT<sup>15</sup>>AAAA (green), or no Cas12a (orange) along  
147 with a phage-specific crRNA. **(h)** Model of AcrVA2 mechanism. Cas12a cleaves phage at specific sites to halt  
148 infection (left). AcrVA2 inhibits Cas12a biogenesis by recognizing conserved residues in its nascent polypeptide  
149 and triggering destruction of its mRNA, allowing phage infection to proceed (middle). Mutating conserved Cas12a  
150 residues prevents binding and downregulation by AcrVA2 but impairs Cas12a anti-phage function, constraining its  
151 ability to escape (right).

152  
153 To find the region of Cas12a that is sufficient for AcrVA2 binding and downregulation, we  
154 truncated MbCas12a from the C-terminus and fused the remaining fragments to RFP. Probing  
155 RFP mRNA revealed that AcrVA2 requires only the first 100 amino acids (~1/14th) of Cas12a to  
156 trigger mRNA downregulation (Fig. 3a). Although the first 30 amino acids of Cas12a were  
157 insufficient for downregulation, this region stably co-precipitated with AcrVA2<sup>H286A</sup>, suggesting  
158 that AcrVA2 recognizes and binds a sequence within this region (Fig. 3a,b). Conversely, a  
159 Cas12a mutant lacking the N-terminal 30 amino acids was well expressed but was no longer  
160 downregulated by AcrVA2 (Extended Data Fig. 6). Altogether, these data indicate that the N-  
161 terminal region of Cas12a is necessary and sufficient for AcrVA2-induced downregulation.

162  
163 Comparing the N-terminal polypeptides of LbCas12a and MbCas12a revealed a conserved  
164 LSKT sequence that interacts directly with crRNA<sup>9</sup> (Fig. 3c). Mutating either L12 or K14 in  
165 MbCas12a to alanine diminished downregulation, while mutating all four of these residues  
166 abolished it (Fig. 3d and Extended Data Fig. 7). As seen with codon-modified versions of Cas12a  
167 (Fig. 1b,c and Extended Data Fig. 2), synonymous mutations at this site had no effect on  
168 downregulation, showing that the amino acid sequence—rather than nucleic acid sequence—of  
169 Cas12a is the recognized substrate (Extended Data Fig. 7). Consistent with a role for the  
170 translated polypeptide, omitting the start codon from Cas12a prevented its translation and  
171 dramatically decreased mRNA downregulation by AcrVA2 (Extended Data Fig. 8).

172  
173 We next assessed whether MbCas12a<sup>LSKT>AAAA</sup> interacts with AcrVA2<sup>H286A</sup> or wildtype  
174 AcrVA2. Because AcrVA2 binds multiple regions in MbCas12a (amino acids 1-30 and 620-  
175 636), we used truncated MbCas12a<sup>560aa</sup> that lacks the PID binding site. While MbCas12a<sup>560aa</sup> is  
176 downregulated by wildtype AcrVA2, co-expression with AcrVA2<sup>H286A</sup> surprisingly increased  
177 MbCas12a<sup>560aa</sup> protein levels, presumably due to the stabilizing effect from their interaction (Fig.  
178 3b,e). Notably, the LSKT>AAAA mutations in the MbCas12a polypeptide sequence abolished  
179 this interaction with AcrVA2 (Fig. 3e and Extended Data Fig. 9).

180

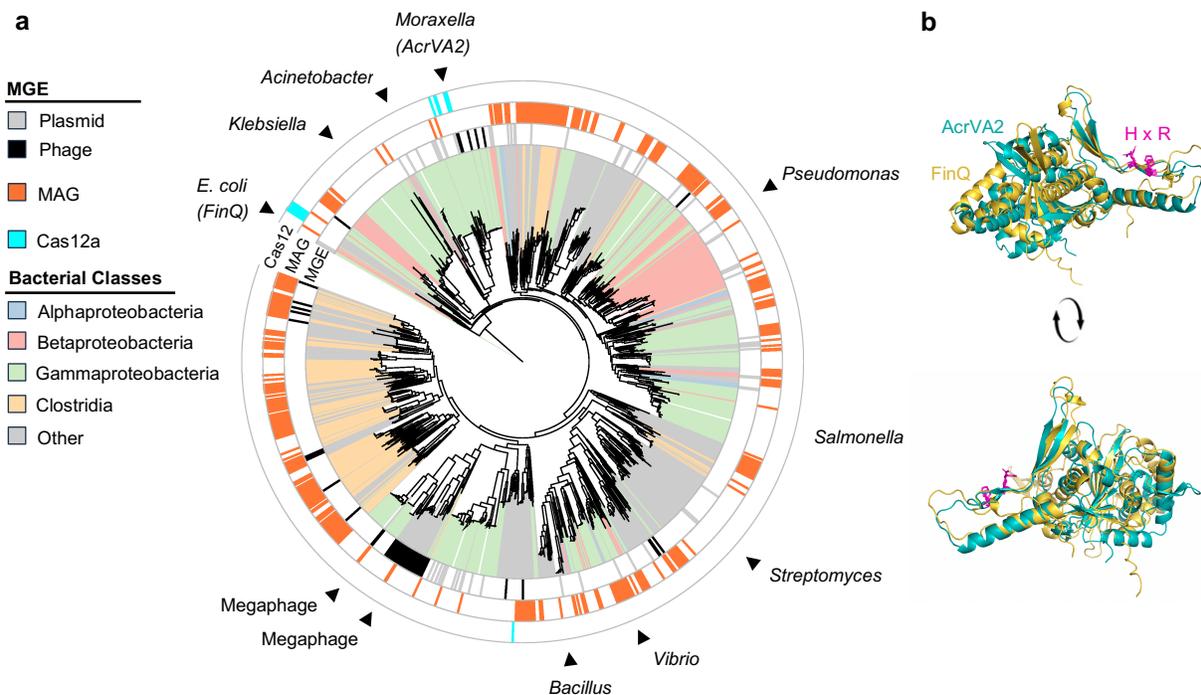

181 Given that LSKT is recognized by AcrVA2, we next tested if these Cas12a residues are  
182 important for anti-phage function. While phage targeting by MbCas12a<sup>LSKT>AAAA</sup> was only  
183 mildly defective at high expression levels (Fig. 3f), this defect became more pronounced at lower  
184 levels of induction (Fig. 3f,g and Extended Data Fig. 10). Across these conditions,  
185 MbCas12a<sup>LSKT>AAAA</sup> was no longer susceptible to inhibition by AcrVA2 (Fig. 3f and Extended  
186 Data Fig. 10). Mutations in L12 and K14 also diminished targeting and susceptibility to  
187 AcrVA2, and the degree of inhibition against the different mutants correlated closely with the  
188 levels of downregulation (Fig. 3d,f). The interaction between K14/T15 and the crRNA may  
189 explain the importance of these residues for CRISPR-Cas12a activity (Fig. 3c).

190

191 Altogether, these data demonstrate that AcrVA2 recognizes and binds the Cas12a N-terminal  
192 polypeptide to drive its mRNA downregulation and inhibition (Fig. 3h). The ability to recognize  
193 conserved and functionally important residues in the target enables AcrVA2 to specifically  
194 downregulate diverse Cas12 orthologs while limiting their ability to escape inhibition.

195

#### 196 AcrVA2 orthologs are broadly distributed on diverse mobile genetic elements

197

198 **Figure 4. AcrVA2 orthologs are encoded on mobile genetic elements across diverse bacteria.** (a) Approximate  
199 maximum likelihood phylogenetic tree of ~1,800 AcrVA2 orthologs. The innermost ring indicates bacterial class by  
200 color, while the adjacent ring indicates the mobile genetic element (MGE) the ortholog is present on (where  
201 annotated). The middle ring indicates if the ortholog is found on a metagenomic assembled genome (MAG), and the  
202 outermost ring indicates if Cas12a was found in the host genome. The relative branch lengths reflect evolutionary  
203 distances between taxa without modification (i.e. tree scale is set to 1) (b) Alignment of predicted structures of  
204 AcrVA2 (teal) and FinQ (yellow) from Alpha Fold using Pymol. Conserved HxR motif is indicated in magenta.  
205

206 Phylogenetic analysis revealed that AcrVA2 is unusually widespread across diverse bacterial  
207 classes and is typically found in bacteria where Cas12a is not present (Fig. 4a). We found  
208 orthologs of AcrVA2 on different types of mobile genetic elements, including plasmids and  
209 megaphages. Notably, the protein FinQ (an AcrVA2 homolog) was previously found on F-like  
210 and I-like plasmids in *E. coli*, where it was shown to inhibit conjugation of F-plasmid<sup>11–13</sup>.  
211 Although the mechanism of inhibition was never determined, FinQ appeared to decrease mRNA  
212 levels of F-plasmid transfer genes<sup>13</sup>.

213

214 Sequence alignments of divergent AcrVA2 orthologs revealed that functionally important  
215 residues in the C-terminus (H286 and R288) are conserved (Extended Data Fig. 11). The  
216 predicted structures of AcrVA2 and FinQ also show notable similarities in the C-terminal  
217 domain (Fig. 4b) and diverge near the N-terminus. These findings suggest that this regulatory  
218 paradigm may be widespread in bacteria against different targets to facilitate conflict between  
219 mobile genetic elements.

220

## 221 Discussion

222 In this study, we have shown that AcrVA2 interrupts Cas12a biogenesis by recognizing  
223 conserved residues in its N-terminal polypeptide and triggering degradation of its mRNA.  
224 Multiple lines of evidence support this: first, AcrVA2 downregulates mRNA of divergent  
225 Cas12a orthologs independently of the promoter and codon sequence. Second, the N-terminal  
226 region of Cas12a is necessary and sufficient for this downregulation and stably binds AcrVA2.  
227 Finally, amino acid mutations (but not synonymous mutations) near the N-terminus of Cas12a  
228 abolish binding, downregulation, and inhibition by AcrVA2. The most straightforward model is  
229 that AcrVA2 recognizes the nascent polypeptide of Cas12a and triggers destruction of its mRNA  
230 before translation is complete. Although surprising, this strategy enables AcrVA2 to recognize a  
231 conserved and functionally important element in Cas12a and destroy it before it is fully  
232 expressed.

233

234 Inhibiting biogenesis is presumably ineffective against pre-existing Cas12a present in the cell.  
235 For the experiments shown here, Cas12a and AcrVA2 were induced simultaneously. However,  
236 the prophage encoding *acrVA2* in *Moraxella bovoculi* also encodes *acrVA1*, which inactivates  
237 crRNA-loaded Cas12a complexes. The dual strategies employed by these co-encoded anti-  
238 CRISPRs to inactivate crRNA-loaded Cas12a complexes (i.e. AcrVA1) and suppress Cas12a  
239 expression (i.e. AcrVA2) likely enable initial infection and stable lysogeny more effectively than  
240 either strategy alone (Extended Data Fig. 12). Dual mechanisms that inactivate complexes and  
241 reduce expression by a different mechanism have also been observed previously for phage-  
242 encoded Cas9 anti-CRISPR proteins<sup>14</sup>.

243

244 Some ribonucleases have previously been reported to bind the ribosomal aminoacylation (A)-site  
245 and cleave mRNAs in response to stress<sup>15</sup>. The nascent chain of DnaA was also shown to

246 modulate translation elongation in response to nutrient availability<sup>16</sup>. To our knowledge,  
247 AcrVA2 is the first example in prokaryotes of a protein triggering mRNA degradation of a  
248 specific substrate upon recognizing its translated polypeptide sequence.

249

250 It remains unclear how AcrVA2 triggers Cas12a mRNA destruction. A similar mechanism has  
251 been demonstrated through multiple studies for tubulin autoregulation in mammalian cells<sup>17–21</sup>,  
252 but the mechanism for mRNA degradation has also not yet been reported. The factors and  
253 pathways involved in this fascinating mechanism will need to be elucidated in future studies.

254

255 The arms race between bacteria and phage has yielded many exciting tools and key biological  
256 discoveries for gene editing and gene regulation. Here, we show a novel strategy for CRISPR-  
257 Cas regulation that may be pervasive in microbial antagonism. The insights from this work can  
258 be applied to achieve constitutive long-term inactivation of nucleases during gene editing and  
259 enable protein-specific gene regulation in bacteria and beyond. As we explore the amazing  
260 microbial diversity in nature, many more discoveries doubtless await.

336

## 337 **Methods**

### 338 **Bacterial strains and growth conditions**

339 *Pseudomonas aeruginosa* strain PAO1 was used in this study. Human codon-modified  
340 MbCas12a and LbCas12a strains (Fig. 1 and Extended Data Fig. 2) were published previously<sup>1,2</sup>,  
341 while other strains were generated in this work (Supplementary Table 1). Strains were grown at  
342 37 °C in lysogeny broth (LB) agar or liquid medium, which was supplemented with 50 µg ml<sup>-1</sup>  
343 gentamicin, 30 µg ml<sup>-1</sup> tetracycline, or 250 µg ml<sup>-1</sup> carbenicillin as needed for plasmid selection  
344 or with 30 µg ml<sup>-1</sup> gentamicin or 100 µg ml<sup>-1</sup> carbenicillin for plasmid maintenance. MbCas12a  
345 and LbCas12a are expressed from the araBAD and tac promoters, respectively, while the crRNA  
346 is expressed from the araBAD promoter. MbCas12a-expressing strains were therefore induced  
347 with 0.3% arabinose, while LbCas12a-expressing strains were induced with 1mM isopropyl β-D-  
348 1-thiogalactopyranoside (IPTG) and 0.3% arabinose.

349

### 350 **Phage isolation**

351 Phage lysates were generated by mixing 10 µl phage lysate with 150 µl overnight culture of *P.*  
352 *aeruginosa* and pre-adsorbing for 15 min at 37 °C. The resulting mixture was then added to  
353 molten 0.7% top agar and plated on 1% LB agar overnight at 30 °C. The phage plaques were  
354 harvested in SM buffer (100 mM NaCl, 8 mM MgSO<sub>4</sub>, 50 mM Tris-HCl, pH 7.5, 0.01%  
355 gelatin), centrifuged to pellet bacteria, treated with chloroform, and stored at 4 °C.

356

### 357 **Strain Engineering**

358 Transformations of *P. aeruginosa* PAO1 strain were performed using standard electroporation  
359 protocols. Briefly, 1 ml of overnight culture was washed twice in 300 mM sucrose or 10%  
360 glycerol and concentrated tenfold. The resulting competent cells were transformed with 30 or  
361 300 ng plasmid (for extrachromosomal uptake or chromosomal integration, respectively),  
362 incubated in antibiotic-free LB for 1 hr at 37 °C, plated on LB agar with selective media, and  
363 grown overnight at 37 °C. Chromosomal integration of pTN7C130 derivatives was achieved by  
364 co-electroporation with pTNS3, as described previously<sup>3,4</sup>. For selection of pTN7C130  
365 chromosomal integration, LB was supplemented with 30 µg ml<sup>-1</sup> gentamicin. For  
366 extrachromosomal selection of pHERD30T or pHERD20T, LB was supplemented with  
367 50 µg ml<sup>-1</sup> gentamicin or 250 µg ml<sup>-1</sup> carbenicillin, respectively.

368

### 369 **Bacteriophage plaque assays**

370 Plaque assays were performed using 1.5% LB agar plates and 0.7% LB top agar, both of which  
371 were supplemented with 10 mM MgSO<sub>4</sub>. 150 µl overnight culture were resuspended in 3-4 ml  
372 molten top agar and plated on LB agar to create a bacterial lawn. Ten-fold serial dilutions of

373 phage were prepared in SM phage buffer (100 mM NaCl, 8 mM MgSO<sub>4</sub>, 50 mM Tris-HCl, pH  
374 7.5, 0.01% gelatin), spotted onto the plate, and incubated overnight at 30 °C. Agar plates were  
375 supplemented with 1mM isopropyl β-D-1-thiogalactopyranoside (IPTG) and 0.3% arabinose for  
376 assays performed with LbCas12a-expressing strains and 0.3% arabinose for assays performed  
377 with MbCas12a-expressing strains. Agar plates were supplemented with 50 μg ml<sup>-1</sup> gentamicin  
378 or 100 μg ml<sup>-1</sup> carbenicillin for pHERD30T and pHERD20T retention, respectively. Anti-  
379 CRISPR activity was assessed by measuring replication of the CRISPR-sensitive phage JBD30  
380 on bacterial lawns relative to the vector control. Plate images were obtained using Gel Doc EZ  
381 Gel Documentation System (BioRad) and Image Lab (BioRad) software.

382

### 383 Cloning

384 The native MbCas12a(237) open reading frame was amplified from genomic DNA of the 237  
385 *Moraxella bovoculi* strain by PCR and cloned into the pTN7C130 vector using HiFi assembly  
386 (NEB). The pTN7C130 vector is a mini-Tn7 vector that integrates into the attTn7 site of *P.*  
387 *aeruginosa* and expresses cargo genes from the araBAD promoter.

388

389 Cas12a mutants were generated from the original vector (pTN7C130-MbCas12a, which  
390 expresses human-codon optimized MbCas12a and a C-terminal 3xHA tag)<sup>1</sup> using site-directed  
391 mutagenesis. Specifically, HA-tagged constructs were generated using round-the-world PCR  
392 with non-overlapping primers encoding the desired mutations. These primers were  
393 phosphorylated using T4 polynucleotide kinase (NEB) prior to PCR, and the resulting amplicons  
394 were digested with DpnI for 1-2 h at 37 °C to destroy the template. The products were ligated  
395 using T4 ligase (NEB) at room temperature for 1 hour or overnight at 16 °C.

396

397 pTN7C130-Cas12a<sup>ΔAUG</sup> and pTN7C130-Cas12a<sup>Δ1-30aa</sup> were generated from the pTN7C130-  
398 MbCas12a vector using round-the-world PCR, as described above. Primers were designed to  
399 omit the start codon (pTN7C130-Cas12a<sup>ΔAUG</sup>) or the first 30 amino acids (pTN7C130-Cas12a<sup>Δ1-</sup>  
400 <sup>30aa</sup>) with an added start codon. Cas12a C-terminal truncations were generated by amplifying the  
401 desired sequence from the pTN7C130-MbCas12a vector and fusing to RFP with Hifi Assembly  
402 (NEB).

403

404 Anti-CRISPR (AcrIIA4, AcrVA1, AcrVA2, and AcrVA2.1) and control genes (RFP and GST)  
405 encoding a C-terminal myc tag were cloned into NcoI and HindIII sites of pHERD20T-myc and  
406 pHERD30T-myc using Gibson Assembly (NEB) or Hifi Assembly (NEB). Backbone vectors  
407 were generated by digestion at the NcoI and HindIII sites or by round-the-world PCR.

408

409 Bacterial transformations for cloning were performed using *E. coli* DH5α (NEB) or XL-1 blues  
410 (QB3 MacroLab) according to the manufacturer's instructions. Plasmids were miniprepmed from  
411 the resulting colonies (Zymo) and Sanger sequenced (Quintara Biosciences).

412

### 413 Immunoprecipitations

414 PAO1 strains were grown overnight at 37°C in LB supplemented with appropriate antibiotics for  
415 plasmid retention. Induction media (50 ml per strain) was inoculated 1:100 with overnight  
416 culture and grown at 37 °C until OD600 0.5 - 1. Samples were normalized by optical density and  
417 harvested at 8,000 x g for 10 min. Pellets were stored at -80°C or immediately resuspended in 1  
418 ml lysis buffer (50 mM Tris, pH 7.5, 250 mM NaCl, 20 mM MgCl<sub>2</sub>, 5% glycerol, 1% NP-40)  
419 supplemented with 0.25 mg/ml lysozyme and mini protease inhibitor cocktail (Roche). Samples  
420 were left on ice for 30 min, then sonicated twice for 10 sec at 30% amplitude at 4 °C (QSonica).  
421 Debris was spun down at 14,000 rpm for 10 minutes at 4 °C and supernatants were collected.  
422 One-tenth of the sample volume was retained for input analysis, and the remaining volume was  
423 rotated overnight at 4 °C with 45 µl of anti-C-myc magnetic beads from Cell Signaling  
424 Technology (Cat. 5698) or Pierce (Cat. 88843) to enrich for myc-tagged constructs. Beads were  
425 washed 4 x 5 min while rotating using 1 ml wash buffer (50 mM Tris, 250 mM NaCl, 20 mM  
426 MgCl<sub>2</sub>, 5% glycerol, 0.1% NP-40) per wash. Eluates were boiled off from the beads in 50µl of  
427 Laemmli buffer (Bio-Rad).

428

#### 429 **Western blots**

430 PAO1 strains were grown overnight at 37 °C in LB supplemented with appropriate antibiotics  
431 for plasmid retention. Induction media (8 ml per strain) was inoculated 1:100 with overnight  
432 culture and grown at 37 °C until OD600 0.5 - 1. Samples were normalized by optical density and  
433 harvested at 8,000 x g for 2 min. Pellets were stored at -80°C or immediately resuspended in 1  
434 ml lysis buffer (50 mM Tris, pH 7.5, 250 mM NaCl, 20 mM MgCl<sub>2</sub>, 5% glycerol, 1% NP-40)  
435 supplemented with 0.25 mg/ml lysozyme and mini protease inhibitor cocktail (Roche). Samples  
436 were left on ice for 30 min, then sonicated twice for 10 sec at 20% amplitude at 4 °C (QSonica).  
437 Debris was spun down at 14,000 rpm for 10 minutes at 4 °C and supernatants were collected.

438

439 Samples (from immunoprecipitation or lysate preparation) were boiled for 10 min in Laemmli  
440 buffer supplemented with BME, separated by SDS-PAGE, and transferred to polyvinylidene  
441 difluoride (PVDF) membranes. Membranes were blocked in blocking buffer (5% milk in TBS  
442 supplemented with 2.5% Tween-20) for 1 h at room temperature and then incubated overnight at  
443 4 °C with primary antibody in blocking buffer. Cas12a-HA was detected using horseradish  
444 peroxidase (HRP)-conjugated HA antibody (Roche) at 1:5000 dilution. LbCas12a was detected  
445 using LbCpf1 (strain ND2006) mouse monoclonal antibody (Cell Signaling Technology,  
446 #91982S) at 1:2000 dilution. Myc-tagged proteins were detected using myc-tag (9B11) mouse  
447 monoclonal antibody (Cell Signaling Technology #2276S) at 1:5000 dilution. RNA polymerase  
448 (RNAP) was detected using anti-E. coli RNA polymerase β (Biolegend, #663905) at 1:5000  
449 dilution. Goat anti-mouse IgG secondary antibody conjugated to horseradish peroxidase (HRP)  
450 (Invitrogen, #62-6520) was used for anti-Myc, anti-LbCpf1, and anti-RNAP primary antibodies.  
451 Horseradish peroxidase (HRP) was detected using enhanced chemiluminescence (ECL) kit  
452 (Pierce). Membranes were stripped between blots by incubation in stripping buffer (Thermo  
453 Fisher) for 10-15 min then washed 2 x 5 min with PBS or TBS-T.

454

## 455 **Protein purification**

456 The plasmids used for MbCas12a(33362) and AcrVA1 protein purification were published  
457 previously (8) and encode the following, in order from the N-terminus: a 10x His tag, maltose  
458 binding protein (MBP), TEV protease cleavage site, the Cas12a sequence, and a C-terminal NLS  
459 sequence for gene editing assays. Anti-CRISPR plasmids for AcrVA2, AcrVA2<sup>H286A</sup>, and  
460 AcrIIA4 protein purification were generated by amplifying the backbone from the AcrVA1  
461 plasmid and cloning in other open reading frames using HiFi assembly (NEB). E. coli Rosetta2  
462 cells freshly transformed with each plasmid were grown overnight in lysogeny broth (LB) and  
463 subcultured in LB until OD<sub>600</sub> ~0.5. Cells were induced with 0.4mM IPTG and grown overnight  
464 at 16 – 20 °C. Cells were harvested and resuspended in lysis buffer (20 mM Tris-HCl, pH 8 at  
465 4°C, 150mM NaCl, 10mM imidazole, 0.5% Triton X-100, 10% glycerol, 1mM TCEP or DTT  
466 supplemented with mini complete EDTA-free protease inhibitor (Roche) and 1mM PMSF), lysed  
467 by sonication, and purified using Ni-NTA resin. The eluted proteins were cleaved with TEV  
468 protease overnight at 4°C (except for AcrVA2, which precipitated out of solution upon  
469 cleavage), and purified by size exclusion chromatography using the following buffer (20mM  
470 HEPES pH 7.5, 150mM KCl, 20mM MgCl<sub>2</sub>, 10% glycerol, 1mM DTT).

471

## 472 **Binding assays**

473 MBP-tagged anti-CRISPR proteins (or control proteins lacking MBP) were incubated with  
474 amylose resin at room temperature for 30 min with occasional shaking. TEV-cleaved  
475 MbCas12a(33362) protein was added and incubated for another 30 min with occasional shaking.  
476 Samples were spun at 600 x g for 2 minutes to collect the flow through. Beads were washed five  
477 times with binding buffer (20 mM Tris, pH 7.5, 200 mM NaCl) and eluted with binding buffer  
478 supplemented with 40 mM maltose. Inputs and eluates were resolved by SDS-polyacrylamide  
479 gel electrophoresis (SDS-PAGE) and stained with Coomassie Blue.

480

## 481 **Cleavage assays *in vitro***

482 *In vitro* Cas12a cleavage assays were performed using purified, TEV-cleaved MbCas12a<sup>33362</sup>  
483 protein and crRNAs that were synthesized commercially (IDT). dsDNA templates were  
484 amplified from plasmids and purified using DNA Clean and Concentrator Kit (Zymo).  
485 Ribonucleoprotein (RNP) formation: crRNA was diluted to 500 nM in 1x cleavage buffer (20  
486 mM HEPES-HCl, pH 7.5, 150 mM KCl, 10 mM MgCl<sub>2</sub>, 0.5 mM TCEP), heated at 70 °C for 5  
487 min, then allowed to cool down to room temperature. crRNA was mixed with 500 nM Cas12a  
488 protein at 1:1 ratio (250 mM final), then incubated at 37 °C for 10 min. Linear template and  
489 purified Acr protein were diluted separately in cleavage buffer to 5 nM and 250 nM,  
490 respectively, and heated for 10 min at 37 °C. Pre-formed RNPs and Acr proteins (each 25 nM  
491 final concentration) were added to template DNA and incubated at 37 °C for 30 min. Reactions  
492 were quenched with 6x Quench Buffer (30% glycerol, 1.2% SDS, 250 mM EDTA). Reactions  
493 were loaded onto 1% TAE agarose gels and resolved by electrophoresis. Gels were post-stained

494 with SYBR Gold (Invitrogen) for 1 hr at room temperature and imaged using BioRad Gel Doc  
495 EZ Imager.

496

497

498

#### 499 **RNA extraction and qRT-PCR**

500 Induction media (8 ml per strain) was inoculated 1:100 with overnight cultures and allowed to  
501 grow to OD<sub>600</sub> of 0.5 - 1. Bacteria were harvested and resuspended in 800 µl water and mixed  
502 1:1 with pre-heated lysis buffer (100 µl of 8x lysis solution [0.3 M sodium acetate, 8% sodium  
503 dodecyl sulfate, 16 mM EDTA] mixed with 700 µl acid phenol:chloroform per sample and  
504 heated at 65 °C for 15 min). The lysate was then incubated at 65 °C for 5 – 10 minutes with  
505 frequent vortexing. Samples were spun at 12,000 x g for 15 minutes at 4 °C and the upper  
506 aqueous layer was collected. Samples were extracted two times with equivalent volumes of  
507 chloroform and incubated overnight at -20 °C with 3 volumes of 100% ethanol. Samples were  
508 harvested at 14,000 rpm for 15 min at 4 °C and washed with 75% ethanol. Pellets were  
509 resuspended in Milli-Q water and assessed for yield and purity using a spectrophotometer.

510

511 Purified RNA was treated for contaminating DNA using the Turbo DNase kit (Invitrogen).  
512 Relative mRNA levels of Cas12a, RFP, and RpoD control were assessed using the Luna  
513 Universal One-Step qRT-PCR kit (New England Biolabs) according to the manufacturer's  
514 instructions. Primers were assessed for efficiency of amplification and controls lacking reverse  
515 transcriptase were used in all experiments. RpoD was used as a loading control to normalize  
516 expression. Experiments were repeated at least three times (from RNA extraction to qRT-PCR  
517 analysis) on randomly chosen colonies (typically from different transformations).

518

#### 519 **RNaseq and analysis**

520 RNA was extracted from bacterial strains expressing MbCas12a and either AcrVA1, AcrVA2,  
521 AcrVA2.1, AcrVA2<sup>H286A</sup>, or AcrIIA4 according to the protocol described above. Purified RNA  
522 was treated for contaminating DNA using Turbo DNase (Invitrogen) for 30 min at 37 °C and  
523 then purified by phenol-chloroform extraction. RNA was prepared for sequencing using the  
524 SMARTER Stranded RNA sequencing kit (Takara Bio) according to the manufacturer's  
525 instructions with the following parameters. Fragmentation was performed for 4 min, and PCR  
526 amplification of the final library was carried out for 10 cycles. Amplified libraries were  
527 quantified using a Qubit 4.0 fluorometer (Life Technologies) and sequenced on an Illumina  
528 HiSeq in single end format (50 bp) with one 6 bp index read.

529

530 Sequencing adapters were trimmed from the reads at the 3' end, and 3 bp were additionally  
531 trimmed from the 5' end of every read to account for the template switching activity of the RT  
532 using cutadapt. Trimmed reads were mapped to the PAO1 reference genome and to the Cas12a

533 CDS using bowtie2. RPKM values were then calculated per gene and mappings were visualized  
534 using IGV.

535

536 The volcano plot was generated by first normalizing RPKM counts against the housekeeping  
537 gene *rpoD*. Genes for which the sum of the normalized counts were less than 10% of *rpoD* were  
538 considered low expression and were removed from further analysis. The ratio change between  
539 the experimental group (AcrVA2 and AcrVA2.1) and control group (AcrIIA4, AcrVA1, and  
540 AcrVA2<sup>H286A</sup>) were calculated for each gene from the normalized counts, and the p-value was  
541 determined by t-Test.

542

### 543 **Phylogenetic analysis**

544 The sequence of AcrVA2 from *Moraxella bovoculi* 58069 was used to query the NCBI non-  
545 redundant protein database with PSI-BLAST (3 rounds, default parameters)<sup>5</sup>. Hits were filtered  
546 to remove any with a sequence length above 2 standard deviations from the mean. MAFFT  
547 alignment was used to align the roughly 1.8k homologs that remained. Because conservation is a  
548 limited domain, L-INS-i iterative refinement method was used with a maxiterate 1000 set<sup>6</sup>.

549 FastTree2 was used to compute an approximate maximum-likelihood phylogenetic tree.

550 Available metadata associated with the proteins were used to classify hits as plasmid, phage or  
551 MAG. Proteins without associated metadata were included but not classified. Visualization was  
552 done with iTol and custom scripts were used to generate additional display features<sup>7</sup>. Sequences  
553 used to make the tree can be found in Supplementary Table 2.

554

### 555 **Protein Alignment**

556 The protein sequence of different orthologues of AcrVA2 were aligned with Clustal Omega and  
557 colored in Jalview using BLOSUM62 scheme. Protein sequences can be found in Supplementary  
558 Table 3.

559

### 560 **Data availability**

561 RNAseq data will be deposited to the Sequence Read Archive prior to publication. All other data  
562 supporting the findings in the Article and the Supplementary Information are available from the  
563 corresponding authors on request.
